

How to interpret

Sensitivity: How many of the actual positives were predicted or identified?
 $TP/(TP+FN)$

Specificity: How many of the actual negatives were predicted or identified?
 $TN/(TN+FP)$

Positive Predictive Value:
The percent of predicted positives that are actually positive.
 $TP/(TP+FP)$

Negative Predictive Value:
The percent of predicted negatives that are actually negative.
 $TN/(TN+FN)$

Precision: How many of the positives are actually positive?
 $TP/(TP+FP)$

Recall: How many of the actual positives were predicted or identified?
 $TP/(TP+FN)$

F1: Balances precision and recall.
One is a perfect score.

Balanced Accuracy:
An average of Sensitivity and Specificity.

Accuracy

Accuracy:
The proportion of correct predictions.
 $(TP + TN)/(Total)$

95% CI:
The range of likely Accuracy values.

P-Value:
The chance Accuracy is random.
Less than 0.05 is good.

Kappa:
How much better than random is the model performance?
One is a perfect score.

Confusion Matrix

		Actual	
		Yes	No
Predicted	Yes	TP	FP
	No	FN	TN
